A weakness of hashing

Problem: For any hash function h, a set of keys exists that can cause the average access time of a hash table to skyrocket.

• An adversary can pick all keys from $\{k \in U : h(k) = i\}$ for some slot i.

IDEA: Choose the hash function at random, independently of the keys.

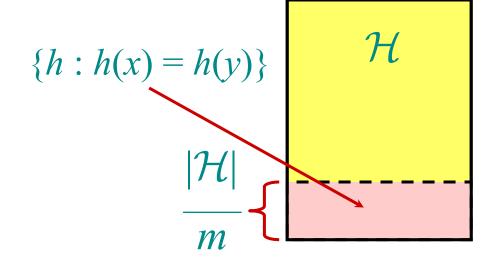

• Even if an adversary can see your code, he or she cannot find a bad set of keys, since he or she doesn't know exactly which hash function will be chosen.

Universal hashing

Definition. Let U be a universe of keys, and let \mathcal{H} be a finite collection of hash functions, each mapping U to $\{0, 1, ..., m-1\}$. We say \mathcal{H} is *universal* if for all $x, y \in U$, where $x \neq y$, we have $|\{h \in \mathcal{H} : h(x) = h(y)\}| = |\mathcal{H}|/m$.

That is, the chance of a collision between x and y is 1/m if we choose h randomly from \mathcal{H} .

Universality is good

Theorem. Let h be a hash function chosen (uniformly) at random from a universal set \mathcal{H} of hash functions. Suppose h is used to hash n arbitrary keys into the m slots of a table T. Then, for a given key x, we have

E[# collisions with x] < n/m.

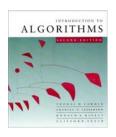

Proof of theorem

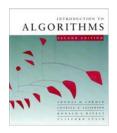

Proof. Let C_x be the random variable denoting the total number of collisions of keys in T with x, and let

 $c_{xy} = \begin{cases} 1 & \text{if } h(x) = h(y), \\ 0 & \text{otherwise.} \end{cases}$

Note:
$$E[c_{xy}] = 1/m$$
 and $C_x = \sum_{y \in T - \{x\}} c_{xy}$.

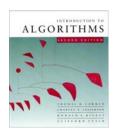

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
 • Take expectation of both sides.

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
 • Take expectation of both sides.

$$= \sum_{y \in T - \{x\}} E[c_{xy}]$$
 • Linearity of expectation.

- expectation.

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
• Take expectation of both sides.
$$= \sum_{y \in T - \{x\}} E[c_{xy}]$$
• Linearity of expectation.
$$= \sum_{y \in T - \{x\}} 1/m$$
• $E[c_{xy}] = 1/m$.

- Linearity of expectation.
 - $E[c_{xv}] = 1/m$.

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
 • Take expectation of both sides.

$$= \sum_{y \in T - \{x\}} E[c_{xy}]$$

$$= \sum_{y \in T - \{x\}} 1/m$$

$$=\frac{n-1}{m}$$
.

- Linearity of expectation.
 - $E[c_{xy}] = 1/m$.

Algebra.

Constructing a set of universal hash functions

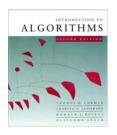

Let m be prime. Decompose key k into r+1digits, each with value in the set $\{0, 1, ..., m-1\}$. That is, let $k = \langle k_0, k_1, ..., k_r \rangle$, where $0 \le k_i < m$.

Randomized strategy:

Pick $a = \langle a_0, a_1, ..., a_r \rangle$ where each a_i is chosen randomly from $\{0, 1, ..., m-1\}$.

Define
$$h_a(k) = \sum_{i=0}^r a_i k_i \mod m$$
. Dot product, modulo m

How big is $\mathcal{H} = \{h_a\}$? $|\mathcal{H}| = m^{r+1}$. — REMEMBER THIS!

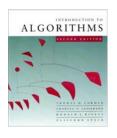

Universality of dot-product hash functions

Theorem. The set $\mathcal{H} = \{h_a\}$ is universal.

Proof. Suppose that $x = \langle x_0, x_1, ..., x_r \rangle$ and y = $\langle y_0, y_1, ..., y_r \rangle$ be distinct keys. Thus, they differ in at least one digit position, wlog position 0. For how many $h_a \in \mathcal{H}$ do x and y collide?

We must have $h_a(x) = h_a(y)$, which implies that

$$\sum_{i=0}^{r} a_i x_i \equiv \sum_{i=0}^{r} a_i y_i \pmod{m}.$$

Equivalently, we have

$$\sum_{i=0}^{r} a_i (x_i - y_i) \equiv 0 \pmod{m}$$

or

$$a_0(x_0 - y_0) + \sum_{i=1}^r a_i(x_i - y_i) \equiv 0 \pmod{m}$$
,

which implies that

$$a_0(x_0 - y_0) \equiv -\sum_{i=1}^r a_i(x_i - y_i) \pmod{m}$$
.

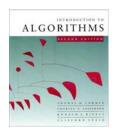

Fact from number theory

Theorem. Let m be prime. For any $z \in \mathbb{Z}_m$ such that $z \neq 0$, there exists a unique $z^{-1} \in \mathbb{Z}_m$ such that

$$z \cdot z^{-1} \equiv 1 \pmod{m}$$
.

Example: m = 7.

$$z$$
 1 2 3 4 5 6 z^{-1} 1 4 5 2 3 6

Back to the proof

We have

$$a_0(x_0 - y_0) \equiv -\sum_{i=1}^r a_i(x_i - y_i) \pmod{m},$$

and since $x_0 \neq y_0$, an inverse $(x_0 - y_0)^{-1}$ must exist, which implies that

$$a_0 \equiv \left(-\sum_{i=1}^r a_i(x_i - y_i)\right) \cdot (x_0 - y_0)^{-1} \pmod{m}.$$

Thus, for any choices of $a_1, a_2, ..., a_r$, exactly one choice of a_0 causes x and y to collide.

Proof (completed)

- **Q.** How many h_a 's cause x and y to collide?
- A. There are m choices for each of $a_1, a_2, ..., a_r$, but once these are chosen, exactly one choice for a_0 causes x and y to collide, namely

$$a_0 = \left(\left(-\sum_{i=1}^r a_i (x_i - y_i) \right) \cdot (x_0 - y_0)^{-1} \right) \mod m.$$

Thus, the number of h 's that cause x and y to collide is $m^r \cdot 1 = m^a = |\mathcal{H}|/m$.

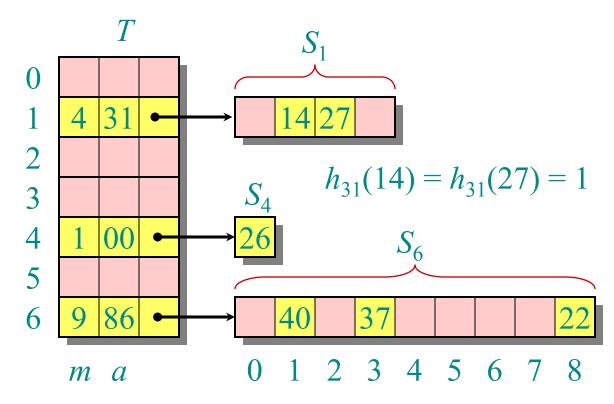

Perfect hashing

Given a set of n keys, construct a static hash table of size m = O(n) such that SEARCH takes $\Theta(1)$ time in the *worst case*.

IDEA: Two-level scheme with universal hashing at both levels.

No collisions at level 2!

Collisions at level 2

Theorem. Let \mathcal{H} be a class of universal hash

functions for a table of size $m = n^2$. Then, if we use a random $h \in \mathcal{H}$ to hash n keys into the table, the expected number of collisions is at most 1/2.

Proof. By the definition of universality, the probability that 2 given keys in the table collide under h is $1/m = 1/n^2$. Since there are $\binom{n}{2}$ pairs of keys that can possibly collide, the expected number of collisions is

$$\binom{n}{2} \cdot \frac{1}{n^2} = \frac{n(n-1)}{2} \cdot \frac{1}{n^2} < \frac{1}{2} . \square$$

No collisions at level 2

Corollary. The probability of no collisions is at least 1/2.

Proof. Markov's inequality says that for any nonnegative random variable *X*, we have

$$\Pr\{X \ge t\} \le E[X]/t.$$

Applying this inequality with t = 1, we find that the probability of 1 or more collisions is at most 1/2.

Thus, just by testing random hash functions in \mathcal{H} , we'll quickly find one that works.

Analysis of storage

For the level-1 hash table T, choose m = n, and let n_i be random variable for the number of keys that hash to slot i in T. By using n_i^2 slots for the level-2 hash table S_i , the expected total storage required for the two-level scheme is therefore

$$E\left[\sum_{i=0}^{m-1}\Theta(n_i^2)\right] = \Theta(n),$$

since the analysis is identical to the analysis from recitation of the expected running time of bucket sort. (For a probability bound, apply Markov.)
